Evaluating Cohen Ter Heide's submission  
IAT 461 Summer 2026  
Aug 12, 2026

## Ratings:

### *Answered Problem Sections: 4/5*

Cohen covered both questions I asked, who's likely to renew and why people joined, and added a spend recommendation on top of that. It's not a 5 because the renewal answer looks stronger on paper than it actually performs once you look into the numbers.

### *Technique judgment: 5/5*

Renewal prediction as supervised classification and survey theme discovery as unsupervised clustering are both the right calls given how I worded the problem. He explains his reasoning behind each choice instead of just going with what I suggested.

### *Evaluation/interpretation quality: 3/5*

The metrics are all reported, AUC, precision, recall, silhouette score, but they're mostly just stated rather than checked against whether they're actually good enough to use. The at-risk list only hits about 51% precision rate.

### *Communication: 4/5*

The notebook is easy to follow and the closing summary is written for a business audience, and the Streamlit dashboard adds a nice layer on top of that. I'd take a point off because the precision issue never makes it into the plain language summary, so someone reading only the conclusion would trust the model more than the numbers support.

### *Open-ended feedback:*

Overall this is solid work. Cohen builds the EDA in a way that actually leads somewhere, channel volume versus retention, attendance trends, distance and family enrollment all set up the argument instead of sitting there as filler. The technique choices are correct and well explained for both problems, and the assumptions and limitations sections are honest rather than glossed over, he's upfront about the synthetic data, the survey response bias, and the fact that none of this proves causation. The strategic ranking system that scores all three business options together and lands on a clear recommendation was a nice addition I didn't ask for directly but found genuinely useful, it turns two separate analyses into one decision instead of leaving me to figure out what to do with the results myself.

My main critique is that the renewal model gets presented a bit more confidently than the numbers back up. A test AUC around 0.71 is decent but not great, and the precision on the at-risk group sitting around 50% means roughly half the members flagged as likely to drop actually weren't going anywhere. That's the kind of thing that needs to be stated plainly next to the recommendation rather than left in the raw classification report for someone to notice on their own, especially since the whole point of the at-risk list is to guide where staff spend their time. The survey clustering has a similar issue, the silhouette score is low and while he does the right thing by treating the themes as exploratory rather than final, he doesn't really say what that weak separation means for how much confidence to place in the six labeled themes. If I were to have Cohen make a revision, it would be tightening up that precision, maybe testing a different threshold or adding features, and being more direct about the tradeoff in the summary.
